Appendix B

Solutions to Exercises

B.1 Exercises from Lecture 1

Exercise 1.1. We should prove that $x$ is robust feasible if and only if it can be extended, by properly chosen $u, v \geq 0$ such that $u - v = x$, to a feasible solution to (1.6.1). First, let $x$ be robust feasible, and let $u_i = \max[x_i, 0], v_i = \max[-x_i, 0]$. Then $u, v \geq 0$ and $u - v = x$. Besides this, since $x$ is robust feasible and uncertainty is element-wise, we have for every $i$

$$
\sum_j \max_{A_{ij}\leq a_{ij} \leq A_{ij}} a_{ij} x_j \leq b_i.
$$

With our $u, v$ we clearly have $\max A_{ij} \leq a_{ij} \leq A_{ij} a_{ij} x_j \leq (\ast)$, so that by ($\ast$) we have $Au - Av \leq b$, so that $(x, u, v)$ is a feasible solution of (1.6.1).

Vice versa, let $(x, u, v)$ be feasible for (1.6.1), and let us prove that $x$ is robust feasible for the original uncertain problem, that is, that the relations ($\ast$) take place. This is immediate, since from $u, v \geq 0$ and $x = u - v$ it clearly follows that $\max A_{ij} \leq a_{ij} \leq A_{ij} a_{ij} x_j \leq (\ast)$, so that the validity of ($\ast$) is ensured by the constraints of (1.6.1). The respective RCs are (equivalent to)

$$(a) \quad [a^n; b^n]^T [x; -1] + \rho\|P^T [x; -1]\|_p \leq 0, \; q = \frac{\rho}{p}$$

$$(b) \quad [a^n; b^n]^T [x; -1] + \rho\|(P^T [x; -1])_+\|_q \leq 0, \; q = \frac{\rho}{p}$$

$$(c) \quad [a^n; b^n]^T [x; -1] + \rho\|P^T [x; -1]\|_\infty \leq 0$$

where for a vector $u = [u_1; \ldots; u_k]$ the vector $(u)_+$ has the coordinates $\max[u_i, 0], i = 1, \ldots, k$. Comment to (c): The uncertainty set in question is nonconvex; since the RC remains intact when a given uncertainty set is replaced with its convex hull, we can replace the restriction $\|\zeta\|_p \leq \rho$ in (c) with the restriction $\zeta \in \text{Conv}\{\zeta : \|\zeta\|_p \leq \rho\} = \{\|\zeta\|_1 \leq \rho\}$, where the concluding equality is due to the following reasons: on one hand, with $p \in (0, 1)$ we have

$$
\|\zeta\|_p \leq \rho \iff \sum_i (|\zeta_i|/\rho)^p \leq 1 \iff |\zeta_i|/\rho \leq 1 \forall i \Rightarrow |\zeta_i|/\rho \leq (|\zeta_i|/\rho)^p
$$

$$
\Rightarrow \sum_i |\zeta_i|/\rho \leq \sum_i (|\zeta_i|/\rho)^p \leq 1,
$$

whence $\text{Conv}\{\|\zeta\|_p \leq \rho\} \subset \{\|\zeta\|_1 \leq \rho\}$. To prove the inverse inclusion, note that all extreme points of the latter set (that is, vectors with all but one coordinates equal to 0 and the remaining coordinate equal $\pm \rho$) satisfy $\|\zeta\|_p \leq 1$. 

283
Exercise 1.3: The RC can be represented by the system of conic quadratic constraints
\[
[a^n; b^n]^T [x; -1] + \rho \sum_j \|u_j\|_2 \leq 0
\]
\[
\sum_j Q_j^{1/2} u_j = P^T [x; -1]
\]
in variables \(x, \{u_j\}_{j=1}^J\).

Exercise 1.4: • The RC of \(i\)-th problem is
\[
\min_x \left\{ -x_1 - x_2 : 0 \leq x_1 \leq \min_{b \in U_i} b_1, 0 \leq x_2 \leq \min_{b \in U_i} b_2, x_1 + x_2 \geq \rho \right\}
\]
We see that both RC’s are identical to each other and form the program
\[
\min_x \{ -x_1 - x_2 : 0 \leq x_1, x_2 \leq 1/3, x_1 + x_2 \geq \rho \}
\]
• When \(\rho = 3/4\), all instances of \(P_1\) are feasible (one can set \(x_1 = b_1, x_2 = b_2\)), while the RC of \(P_2\) is not so, so that there is a gap. In contrast to this, \(P_2\) has infeasible instances, and its RC is infeasible; in this case, there is no gap.
• When \(\rho = 2/3\), the (common) RC of the two problems \(P_1, P_2\) is feasible with the unique feasible solution \(x_1 = x_2 = 1/3\) and the optimal value \(-2/3\). Since every instance of \(P_1\) has a feasible solution \(x_1 = b_1, x_2 = b_2\), the optimal value of the instance is \(\leq -b_1 - b_2 \leq -1\), so that there is a gap. In contrast to this, the RC is an instance of \(P_2\), so that in this case there is no gap.

Exercise 1.5: • Problem \(P_2\) has a constraint-wise uncertainty and is the constraint-wise envelope of \(P_1\).
• Proof for item 2: Let us prove first that if all the instances are feasible, then so is the RC. Assume that the RC is infeasible. Then for every \(x \in X\) there exists \(i = i_x\) and a realization \([a^T_{i_x}, b_{i_x}] \in U_{i_x}\) of the uncertain data of \(i\)-th constraint such that
\[
a^T_{i_x} x' - b_{i_x} > 0
\]
when \(x' = x\) and consequently when \(x'\) belongs to a small enough neighborhood \(U_x\) of \(x\). Since \(X\) is a convex compact set, we can find a finite collection of \(x_j \in X\) such that the corresponding neighborhoods \(U_{x_j}\) cover the entire \(X\). In other words, we can points out finitely many linear forms
\[
f_\ell(x) = a^T_{i_x} x - b_{i_x}, \ell = 1, ..., L,
\]
such that \([a^T_{i_x}, b_{i_x}] \in U_{i_x}\) and the maximum of the forms over \(\ell = 1, ..., L\) is positive at every point \(x \in X\). By standard facts on convexity it follows that there exists a convex combination of our forms
\[
f(x) = \sum_{\ell=1}^L \lambda_\ell [a^T_{i_x} x - b_{i_x}]
\]
which is positive everywhere on \(X\). Now let \(I_i = \{\ell : i = i_\ell\}\) and \(\mu_i = \sum_{\ell \in I_i} \lambda_\ell\). For \(i\) with \(\mu_i > 0\), let us set
\[
[a^T_{i_x}, b_i] = \sum_{\ell \in I_i} \frac{\lambda_\ell}{\mu_i} [a_{i_x}, b_{i_\ell}],
\]
so that \([a_i^T, b_i] \in \mathcal{U}_i\) (since the latter set is convex). For \(i\) with \(\mu_i = 0\), let \([a_i^T, b_i]\) be a whatever point of \(\mathcal{U}_i\). Observe that by construction

\[
f(x) \equiv \sum_{i=1}^{m} \mu_i[a_i^T x - b_i].
\]

Now, since the uncertainty is constraint-wise, the matrix \([A, b]\) with the rows \([a_i^T, b_i]\) belongs to \(\mathcal{U}\) and thus corresponds to an instance of \(\mathcal{P}\). For this instance, we have

\[
\mu^T[Ax - b] = f(x) > 0 \ \forall x \in X,
\]

so that no \(x \in X\) can be feasible for the instance; due to the origin of \(X\), this means that the instance we have built is infeasible, same as the RC.

Now let us prove that if all instances are feasible, then the optimal value of the RC is the supremum, let it be called \(\tau\), of the optimal values of instances (this supremum clearly is achieved and thus is the maximum of optimal values of instances). Consider the uncertain problem \(\mathcal{P}'\) which is obtained from \(\mathcal{P}\) by adding to every instance the (certain!) constraint \(c^T x \leq \tau\). The resulting problem still is with constraint-wise uncertainty, has feasible instances, and feasible solutions of an instance belong to \(X\). By what we have already proved, the RC of \(\mathcal{P}'\) is feasible; but a feasible solution to the latter RC is a robust feasible solution of \(\mathcal{P}\) with the value of the objective \(\leq \tau\), meaning that the optimal value in the RC of \(\mathcal{P}\) is \(\leq \tau\). Since the strict inequality here is impossible due to the origin of \(\tau\), we conclude that the optimal value of the RC of \(\mathcal{P}\) is equal to the maximum of optimal values of instances of \(\mathcal{P}\), as claimed.

### B.2 Exercises from Lecture 2

#### Exercise 2.1:

W.l.o.g., we may assume \(t > 0\). Setting \(\phi(s) = \cosh(ts) - [\cosh(t) - 1]s^2\), we get an even function such that \(\phi(-1) = \phi(0) = \phi(1) = 1\). We claim that \(\phi(s) \leq 1\) when \(-1 \leq s \leq 1\).

Indeed, otherwise \(\phi\) attains its maximum on \([-1, 1]\) at a point \(\bar{s} \in (0, 1)\), and \(\phi''(\bar{s}) \leq 0\). The function \(g(s) = \phi'(s)\) is convex on \([0, 1]\) and \(g(0) = g(\bar{s}) = 0\). The latter, due to \(g'(\bar{s}) \leq 0\), implies that \(g(s) = 0, 0 \leq s \leq \bar{s}\). Thus, \(\phi\) is constant on a nontrivial segment, which is not the case.

For a symmetric \(P\) supported on \([-1, 1]\) with \(\int s^2 dP(s) \equiv \bar{\nu}^2 \leq \nu^2\) we have, due to \(\phi(s) \leq 1, -1 \leq s \leq 1\):

\[
\int \exp\{ts\} dP(s) = \int_{-1}^{1} \cosh(ts) dP(s)
= \int_{-1}^{1} [\cosh(ts) - (\cosh(t) - 1)s^2] dP(s) + (\cosh(t) - 1) \int_{-1}^{1} s^2 dP(s)
\leq \int_{-1}^{1} dP(s) + (\cosh(t) - 1)\bar{\nu}^2 \leq 1 + (\cosh(t) - 1)\nu^2,
\]

as claimed in example 8. Setting \(h(t) = \log(\nu^2 \cosh(t) + 1 - \nu^2)\), we have \(h(0) = h'(0) = 0\), \(h''(t) = \frac{\nu^2 (\nu^2 + (1 - \nu^2) \cosh(t))}{(\nu^2 \cosh(t) + 1 - \nu^2)^2}\), \(\max_t h''(t) = \left\{ \begin{array}{l} \nu^2, \\ \frac{1}{4} \left[ 1 + \frac{\nu^4}{1 - 2\nu^2} \right] \leq \frac{1}{3}, \quad \nu^2 \geq \frac{1}{3} \end{array} \right. \), whence \(\Sigma(3)(\nu) \leq 1\).

#### Exercise 2.2:

Here are the results:
Exercise 2.3: Here are the results:

</tbody>
</table>

Exercise 2.4: In the case of (a), the optimal value is $t_a = \sqrt{n} \text{ErfInv} (\epsilon)$, since for a feasible $x$ we have $\xi^n[x] \sim N(0,n)$. In the case of (b), the optimal value is $t_b = n \text{ErfInv}(n\epsilon)$. Indeed, the rows in $B_n$ are of the same Euclidean length and are orthogonal to each other, whence the columns are orthogonal to each other as well. Since the first column of $B_n$ is the all-one vector, the conditional on $\eta$ distribution of $\xi = \sum_j \hat{\zeta}_j$ has the mass 1/n at the point $n\eta$ and the mass $(n-1)/n$ at the origin. It follows that the distribution of $\xi$ is the convex combination of the Gaussian distribution $N(0,n^2)$ and the unit mass, sitting at the origin, with the weights $1/n$ and $(n-1)/n$, respectively, and the claim follows.

The numerical results are as follows:

<table>
<thead>
<tr>
<th>n</th>
<th>ε</th>
<th>$t_a$</th>
<th>$t_b$</th>
<th>$t_b/t_a$</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Exercise 2.5: In the notation of section 2.4.2, we have

$$
\Phi(w) = \ln \left( \mathbb{E}\{\exp\left(\sum_\ell w_\ell \zeta_\ell\right)\} \right) = \sum_\ell \lambda_\ell (\exp\{w_\ell\} - 1) = \max_u[w^T u - \phi(u)],
$$

$$
\phi(u) = \max_w[w^T w - \Phi(w)] = \begin{cases} \sum_\ell [u_\ell \ln(u_\ell/\lambda_\ell) - u_\ell + \lambda_\ell], & u \geq 0 \\ +\infty, & \text{otherwise.} \end{cases}
$$

Consequently, the Bernstein approximation is

$$
\inf_{\beta > 0} \left[ z_0 + \beta \sum_\ell \lambda_\ell (\exp\{w_\ell/\beta\} - 1) + \beta \ln(1/\epsilon) \right] \leq 0,
$$
or, in the RC form,
\[
z_0 + \max_u \left\{ w^T u : u \in \mathbb{Z}_+ = \{ u \geq 0, \sum_{\ell} [u_\ell \ln(u_\ell/\lambda_\ell) - u_\ell + \lambda_\ell] \leq \ln(1/\epsilon) \} \right\} \leq 0.
\]

**Exercise 2.6:** $w(\epsilon)$ is the optimal value in the chance constrained optimization problem
\[
\min_{w_0} \left\{ w_0 : \text{Prob}\{-w_0 + \sum_{\ell=1}^{L} c_\ell \zeta_\ell \leq 0\} \geq 1 - \epsilon \right\},
\]
where $\zeta_\ell$ are independent Poisson random variables with parameters $\lambda_\ell$.

When all $c_\ell$ are integral in certain scale, the random variable $\zeta_L = \sum_{\ell=1}^{L} c_\ell \zeta_\ell$ is also integral in the same scale, and we can compute its distribution recursively in $L$:
\[
p_0(i) = \begin{cases} 1, & i = 0 \\ 0, & i \neq 0 \end{cases},
p_k(i) = \sum_{j=0}^{\infty} p_{k-1}(i - c_\ell j) \frac{\lambda_k^j}{j!} \exp\{-\lambda_k\};
\]
(in computations, $\sum_{j=0}^{\infty} q$ should be replaced with $\sum_{j=0}^{N}$ with appropriately large $N$).

With the numerical data in question, the expected value of per day requested cash is $c^T \lambda = 7,000$, and the remaining requested quantities are listed below:

<table>

“BCV” stands for the bridged Bernstein-CVaR, “B” — for the Bernstein, and “E” — for the $(1 - \epsilon)$-reliable empirical bound on $w(\epsilon)$. The BCV bound corresponds to the generating function $\gamma_{16,10}(\cdot)$, see p. 64. The percents represent the relative differences between the bounds and $w(\epsilon)$.

All bounds are right-rounded to the closest integers.

**Exercise 2.7:** The results of computations are as follows (as a benchmark, we display also the results of Exercise 2.6 related to the case of independent $\zeta_1, \ldots, \zeta_L$):

<table>

</table>

Percents display relative differences between the bounds and $w(\epsilon)$.
Exercise 2.8. Part 1: By Exercise 2.5, the Bernstein upper bound on $w(\epsilon)$ is

\[
B(\lambda) = \inf_{\beta > 0} \left\{ \sum_{\ell} \lambda_\ell \exp\left\{ c_\ell / \beta \right\} - 1 + \beta \ln(1/\epsilon) \mid \beta \right\} \leq 0
\]

The “ambiguous” Bernstein upper bound on $w(\epsilon)$ is therefore

\[
B^*(\lambda) = \max_{\lambda \in A} \inf_{\beta > 0} \left\{ \sum_{\ell} \lambda_\ell \exp\left\{ c_\ell / \beta \right\} - 1 + \beta \ln(1/\epsilon) \mid \beta \right\} = \inf_{\beta > 0} \beta \left( \sum_{\ell} \lambda_\ell \exp\left\{ c_\ell / \beta \right\} - 1 + \ln(1/\epsilon) \right)
\]

where the swap of $\inf_{\beta > 0}$ and $\max_{\lambda \in A}$ is justified by the fact that the function $\beta \sum_{\ell} \lambda_\ell \exp\left\{ c_\ell / \beta \right\} - 1 + \beta \ln(1/\epsilon)$ is concave in $\lambda$, convex in $\beta$ and by the compactness and convexity of $\Lambda$.

Part 2: We should prove that if $\Lambda$ is a convex compact set in the domain $\lambda \geq 0$ such that

\[
\max_{\lambda \in A} f(\lambda) \leq 0 \Rightarrow \Pr_{\lambda \sim P} \left\{ f(\lambda) \leq 0 \right\} \geq 1 - \delta
\]

then, setting $w_0 = B(\lambda)$, one has

\[\Pr_{\lambda \sim P} \left\{ \lambda : \Pr_{\zeta \sim P_\lambda} \left\{ \sum_{\ell} \zeta_\ell c_\ell > w_0 \right\} > \epsilon \right\} \leq \delta\]

It suffices to prove that under our assumptions on $\Lambda$ inequality (?) is valid for all $w_0 > B(\lambda)$. Given $w_0 > B(\lambda)$ and invoking the second relation in (*)&, we can find $\beta > 0$ such that

\[
\beta \left( \sum_{\ell} \lambda_\ell \exp\left\{ c_\ell / \beta \right\} - 1 + \ln(1/\epsilon) \right) \leq w_0,
\]

or, which is the same,

\[
\left\{ -w_0 + \beta \ln(1/\epsilon) \right\} + \max_{\lambda \in A} \beta \left( \sum_{\ell} \lambda_\ell \exp\left\{ c_\ell / \beta \right\} - 1 \right) \leq 0,
\]

which, by (1) as applied to the affine form

\[
f(\lambda) = \left\{ -w_0 + \beta \ln(1/\epsilon) \right\} + \sum_{\ell} \lambda_\ell \beta \left( \exp\left\{ c_\ell / \beta \right\} - 1 \right),
\]

implies that

\[\Pr_{\lambda \sim P} \left\{ f(\lambda) > 0 \right\} \leq \delta.\]

It remains to note that when $\lambda \geq 0$ is such that $f(\lambda) \leq 0$, the result of Exercise 2.5 states that

\[\Pr_{\zeta \sim P_{\lambda_1} \times \ldots \times P_{\lambda_m}} \left\{ \sum_{\ell} \zeta_\ell c_\ell > 0 \right\} \leq \epsilon.
\]

Thus, when $w_0 > B(\lambda)$, the set of $\lambda$’s in the left hand side of (?) is contained in the set $\{ \lambda \geq 0 : f(\lambda) > 0 \}$, and therefore (?) is readily given by (**).
B.3 Exercises from Lecture 3

Exercise 3.1: Let $S[\cdot]$ be a safe tractable approximation of $(C_Z[\cdot])$ tight within the factor $\vartheta$. Let us verify that $S[\lambda \varrho]$ is a safe tractable approximation of $(C_Z[\rho])$ tight within the factor $\lambda \varrho$. All we should prove is that (a) if $x$ can be extended to a feasible solution to $S[\lambda \varrho]$, then $x$ is feasible for $(C_Z[\rho])$, and that (b) if $x$ cannot be extended to a feasible solution to $S[\lambda \varrho]$, then $x$ is not feasible for $(C_Z[\lambda \varrho])$. When $x$ can be extended to a feasible solution of $S[\lambda \varrho]$, $x$ is feasible for $(C_Z[\lambda \varrho])$, and since $\rho Z \subset \lambda \gamma \rho Z$, $x$ is feasible for $(C_Z[\rho])$ as well, as required in (a). Now assume that $x$ cannot be extended to a feasible solution of $S[\lambda \varrho]$. Then $x$ is not feasible for $(C_Z[\lambda \varrho])$, and since the set $\vartheta \lambda \gamma \rho Z$ is contained in $\vartheta \lambda \rho Z$, $x$ is not feasible for $(C_Z[\lambda \varrho])$, as required in (b).

Exercise 3.2: 1) Consider the ellipsoid

$$Z_\ast = \{ \zeta : \zeta^T \left[ \sum_i Q_i \right] \zeta \leq M \}.$$  

We clearly have $M^{-1/2} Z_\ast \subset $ $Z \subset Z_\ast$; by assumption, $(C_Z[\cdot])$ admits a safe tractable approximation tight within the factor $\vartheta$, and it remains to apply the result of Exercise 3.1.

2) This is a particular case of 1) corresponding to $\zeta^T Q_i \zeta = \zeta_i^2$, $1 \leq i \leq M = \dim \zeta$.

3) Let $Z = \bigcap_{i=1}^M E_i$, where $E_i$ are ellipsoids. Since $Z$ is symmetric w.r.t. the origin, we also have $Z = \bigcap_{i=1}^M [E_i \cap (-E_i)]$. We claim that for every $i$, the set $E_i \cap (-E_i)$ contains an ellipsoid $F_i$ centered at the origin and such that $E_i \cap (-E_i) \subset \sqrt{2} F_i$, and that this ellipsoid $F_i$ can be easily found. Believing in the claim, we have

$$Z_\ast = \bigcap_{i=1}^M F_i \subset Z \subset \sqrt{2} \bigcap_{i=1}^M F_i.$$  

By 1), $(C_Z[\cdot])$ admits a safe tractable approximation with the tightness factor $\vartheta \sqrt{M}$; by Exercise 3.1, $(C_Z[\cdot])$ admits a safe tractable approximation with the tightness factor $\vartheta \sqrt{2M}$.

It remains to support our claim. For a given $i$, applying nonsingular linear transformation of variables, we can reduce the situation to the one where $E_i = B + e$, where $B$ is the unit Euclidean ball, centered at the origin, and $\|e\|_2 < 1$ (the latter inequality follows from $0 \in \text{int} Z \subset \text{int} (E_i \cap (-E_i))$). The intersection $G = E_i \cap (-E_i)$ is a set that is invariant w.r.t. rotations around the axis $\Re e$; a 2-D cross-section $H$ of $G$ by a 2D plane $\Pi$ containing the axis is a 2-D solid symmetric w.r.t. the origin. It is well known that for every symmetric w.r.t. 0 solid $Q$ in $\mathbb{R}^d$ there exists a centered at 0 ellipsoid $E$ such that $E \subset Q \subset \sqrt{d} E$. Therefore there exists (and in fact can easily be found) an ellipsoid $I$, centered at the origin, that is contained in $H$ and is such that $\sqrt{2} I$ contains $H$. Now, the ellipsoid $I$ is the intersection of $\Pi$ and an ellipsoid $F_i$ that is invariant w.r.t. rotations around the axis $\Re e$, and $F_i$ clearly satisfies the required relations $F_i \subset E_i \cap (-E_i) \subset \sqrt{2} F_i$.  

\footnote{In fact, the factor $\sqrt{2}$ in the latter relation can be reduced to $2/\sqrt{3} < \sqrt{2}$, see Solution to Exercise 3.4.}
Exercise 3.3: With \( y \) given, all we know about \( x \) is that there exists \( \Delta \in \mathbb{R}^{p \times q} \) with \( \| \Delta \|_{2,2} \leq \rho \) such that \( y = B_n[x; 1] + L^T \Delta R[x; 1] \), or, denoting \( w = \Delta R[x; 1] \), that there exists \( w \in \mathbb{R}^p \) with \( w^T w \leq \rho^2 \| x \|_2 R^T R \| x \|_2 \) such that \( y = B_n[x; 1] + L^T w \). Denoting \( z = [x; w] \), all we know about the vector \( z \) is that it belongs to a given affine plane \( Az = a \) and satisfies the quadratic inequality \( z^T C z + 2c^T z + d \leq 0 \), where \( A = [A_n, L^T] \), \( a = y - b_n \), and

\[
[\xi; \omega]^T C [\xi; \omega] + 2c^T [\xi; \omega] + d \equiv \omega^T \omega - \rho^2 \| \xi \|_2 R^T R \| \xi \|_2, \quad [\xi; \omega] \in \mathbb{R}^{n+p}.
\]

Using the equations \( Az = a \), we can express the \( n + p \) \( z \)-variables via \( k \leq n + p \) \( u \)-variables:

\[
Az = a \Leftrightarrow \exists u \in \mathbb{R}^k : z = Eu + e.
\]

Plugging \( z = Eu + e \) into the quadratic constraint \( z^T C z + 2c^T z + d \leq 0 \), we get a quadratic constraint \( u^T Fu + 2f^T u + g \leq 0 \) on \( u \). Finally, the vector \( Qx \) we want to estimate can be represented as \( Pu \) with easily computable matrix \( P \). The summary of our developments is as follows:

(1) Given \( y \) and the data describing \( B \), we can build \( k \), a matrix \( P \) and a quadratic form \( u^T Fu + 2f^T u + g \leq 0 \) on \( \mathbb{R}^k \) such that the problem of interest becomes the problem of the best, in the worst case, \( \| \cdot \|_2 \)-approximation of \( Pu \), where unknown vector \( u \in \mathbb{R}^k \) is known to satisfy the inequality \( u^T Fu + 2f^T u + g \leq 0 \).

By (1), our goal is to solve the semi-infinite optimization program

\[
\min_{t, w} \{ \| Pu - v \|_2 \leq t \forall (u : u^T Fu + 2f^T u + g \leq 0) \}.
\]

Assuming that \( \inf_u [u^T Fu + 2f^T u + g] \leq 0 \) and applying the inhomogeneous version of S-Lemma, the problem becomes

\[
\min_{t, w, \lambda} \left\{ t \geq 0 : \begin{bmatrix} \lambda F - P^T P & \lambda f - P^T v \\ \lambda f - v^T P & \lambda g + t^2 - v^T v \end{bmatrix} \geq 0, \lambda \geq 0 \right\}.
\]

Passing from minimization of \( t \) to minimization of \( \tau = t^2 \), the latter problem becomes the semidefinite program

\[
\min_{\tau, w, \lambda, s} \left\{ \tau : \begin{bmatrix} \lambda F - P^T P & \lambda f - P^T v \\ \lambda f - v^T P & \lambda g + \tau - s \end{bmatrix} \geq 0 \right\}.
\]

In fact, the problem of interest can be solved by pure Linear Algebra tools, without Semidefinite optimization. Indeed, assume for a moment that \( P \) has trivial kernel. Then (1) is feasible if and only if the solution set \( S \) of the quadratic inequality \( \phi(u) \equiv u^T Fu + 2f^T u + g \leq 0 \) in variables \( u \) is nonempty and bounded, which is the case if and only if this set is an ellipsoid \( (u - c)^T Q(u - c) \leq r^2 \) with \( Q \succ 0 \) and \( r \geq 0 \); whether this indeed is the case and what are \( c, Q, r \), if any, can be easily found out by Linear Algebra tools. The image \( PS \) of \( S \) under the mapping \( P \) also is an ellipsoid (perhaps “flat”) centered at \( v_0 = Pc \), and the optimal solution to (1) is \( (t_0, \nu_0) \), where \( t_0 \) is the largest half-axis of the ellipsoid \( PS \). In the case when \( P \) has a kernel, let \( E \) be the orthogonal complement to \( \ker P \), and \( \tilde{P} \) be the restriction of \( P \) onto \( E \); this mapping has a trivial kernel. Problem (1) clearly is equivalent to

\[
\min_{t, w} \{ \| \tilde{P} \hat{u} - v \|_2 \leq t \forall (\hat{u} : \exists w \in \ker P : \phi(\hat{u} + w) \leq 0) \}.
\]
The set
\[ \hat{U} = \{ \hat{u} \in E : \exists w \in \text{Ker} P : \phi(\hat{u} + w) \leq 0 \} \]
clearly is given by a single quadratic inequality in variables \( \hat{u} \in E \), and (**) reduces to a similar problem with \( E \) in the role of the space where \( u \) lives and \( \hat{P} \) in the role of \( P \), and we already know how to solve the resulting problem.

**Exercise 3.4:** In view of Theorem 3.9, all we need to verify is that \( Z \) can be “safely approximated” within an \( O(1) \) factor by an intersection \( \hat{Z} \) of \( O(1)J \) ellipsoids centered at the origin: there exists \( \hat{Z} = \{ \eta : \eta^T \hat{Q} j \eta \leq 1, 1 \leq j \leq \hat{J} \} \) with \( \hat{Q}_j \geq 0, \sum_j \hat{Q}_j > 0 \) such that
\[ \theta^{-1} \hat{Z} \subset Z \subset \hat{Z}, \]
with an absolute constant \( \theta \) and \( \hat{J} \leq O(1)J \). Let us prove that the just formulated statement holds true with \( \hat{J} = J \) and \( \theta = \sqrt{3}/2 \). Indeed, since \( Z \) is symmetric w.r.t. the origin, setting \( E_j = \{ \eta : (\eta - a_j)^T Q_j (\eta - a_j) \leq 1 \} \), we have
\[ Z = \bigcap_{j=1}^J E_j = \bigcap_{j=1}^J (-E_j) = \bigcap_{j=1}^J (E_j \cap [-E_j]); \]
all we need is to demonstrate that every one of the sets \( E_j \cap [-E_j] \) is in between two proportional ellipsoids centered at the origin with the larger one being at most \( 2/\sqrt{3} \) multiple of the smaller one. After an appropriate linear one-to-one transformation of the space, all we need to prove is that if \( E = \{ \eta \in \mathbb{R}^d : (\eta_1 - r)^2 + \sum_{j=2}^k \eta_j^2 \leq 1 \} \) with \( 0 \leq r < 1 \), then we can point out the set \( F = \{ \eta : \eta_1^2/a^2 + \sum_{j=2}^k \eta_j^2/b^2 \leq 1 \} \) such that
\[ \frac{\sqrt{3}}{2} F \subset E \cap [-E] \subset F. \]

When proving the latter statement, we lose nothing when assuming \( k = 2 \). Renaming \( \eta_1 \) as \( y \), \( \eta_2 \) as \( x \) and setting \( h = 1 - r \in (0,1) \) we should prove that the “loop” \( \mathcal{L} = \{ [x:y] : |y| + (1-h)^2 + x^2 \leq 1 \} \) is in between two proportional ellipsoids centered at the origin with the ratio of linear sizes \( \theta \leq 2/\sqrt{3} \). Let us verify that we can take as the smaller of these ellipses the ellipsoid
\[ \mathcal{E} = \{ [x:y] : y^2/h^2 + x^2/(2h-h^2) \leq \mu^2 \}, \mu = \sqrt{\frac{3-h}{4-2h}}, \]
and to choose \( \theta = \mu^{-1} \) (so that \( \theta \leq 2/\sqrt{3} \) due to \( 0 < h \leq 1 \)). First, let us prove that \( \mathcal{E} \subset \mathcal{L} \). This inclusion is evident when \( h = 1 \), so that we can assume that \( 0 < h < 1 \). Let \( [x:y] \in \mathcal{E} \), and let \( \lambda = \frac{2(1-h)}{h} \). We have
\[
\begin{align*}
y^2/h^2 + x^2/(2h-h^2) &\leq \mu^2 \Rightarrow \begin{cases} y^2 \leq h^2[\mu^2 - x^2/(2h-h^2)] & (a) \\
x^2 \leq \mu^2 h(2-h) & (b) \end{cases} \\
(|y| + (1-h))^2 + x^2 &\leq y^2 + 2|y|(1-h) + (1-h)^2 \leq y^2 + \lambda y^2 + \frac{1}{\lambda}(1-h)^2 \\
+ (1-h)^2 &\leq y^2 + 2 \left[ \frac{2-h}{h^2} \right] h(2-h) + x^2 \\
&\leq \left[ \mu^2 - \frac{2-h}{h^2} \right] (2h-h^2) + \frac{(2-h)(1-h)}{2} + x^2 \equiv q(x^2),
\end{align*}
\]
where the concluding \( \leq \) is due to \( (a) \). Since \( 0 \leq x^2 \leq \mu^2 (2h-h^2) \) by \( (b) \), \( q(x^2) \) is in-between its values for \( x^2 = 0 \) and \( x^2 = \mu^2 (2h-h^2) \), and both these values with our \( \mu \) are equal to 1. Thus, \( [x:y] \in \mathcal{L} \).
It remains to prove that $\mu^{-1}E \supset L$, or, which is the same, that when $[x; y] \in L$, we have $[\mu x; \mu y] \in E$. Indeed, we have
\[
\[|y| + (1-h))^2 + x^2 \leq 1 \Rightarrow |y| \leq h \& x^2 \leq 1 - y^2 - 2|y|(1-h) - (1-h)^2 \]
\[
x^2 \leq 2h - h^2 - y^2 - 2|y|(1-h) \Rightarrow \mu^2 \left[ \frac{y^2}{h^2} + \frac{x^2}{2h-h^2} \right] = \mu^2 \left[ \frac{y^2(2-h)+hx^2}{h^2(2-h)} \right] \leq \mu^2 \frac{\mu^2 h^2(2-h)+2(1-h)|y|^2 - |y|h}{h^2(2-h)} \leq \mu^2
\]
as claimed.

**Exercise 3.5:** 1) We have
\[
\text{EstErr} = \sup_{v \in V, A \in A} \sqrt{v^T (GA-I)^T (GA-I)v + \text{Tr}(G^T \Sigma G)} = \sup_{A \in A, u \in \mathbb{R}^n} \sqrt{v^T Q^{-1/2}(GA-I)^T (GA-I)Q^{-1/2}u + \text{Tr}(G^T \Sigma G)}
\]
\[
= \sqrt{\sup_{A \in A} \|(GA-I)Q^{-1/2}\|_{2,2}^2 + \text{Tr}(G^T \Sigma G)}.
\]
By the Schur Complement Lemma, the relation $\|(GA-I)Q^{-1/2}\|_{2,2} \leq \tau$ is equivalent to the LMI
\[
\begin{bmatrix}
\tau I & (GA-I)Q^{-1/2} \\
(GA-I)Q^{-1/2} & \tau I
\end{bmatrix} \succeq 0,
\]
and therefore the problem of interest can be posed as the semi-infinite semidefinite program
\[
\min_{t, \tau, b, G} \left\{ t : \begin{bmatrix} \tau^2 + \delta^2 \leq t, \text{Tr}(G^T \Sigma G) \leq \delta \\
\tau I \\
(GA-I)Q^{-1/2} \\
\tau I
\end{bmatrix} \succeq 0 \forall A \in A \right\},
\]
which is nothing but the RC of the uncertain semidefinite program
\[
\begin{bmatrix}
\min_{t, \tau, b, G} \left\{ t : \begin{bmatrix} \tau^2 + \delta^2 \leq t, \text{Tr}(G^T \Sigma G) \leq \delta \\
\tau I \\
(GA-I)Q^{-1/2} \\
\tau I
\end{bmatrix} \succeq 0 \right\} : A \in A \right\}.
\]
In order to reformulate the only semi-infinite constraint in the problem in a tractable form, note that with $A = A_n + L^T \Delta R$ we have
\[
\mathcal{N}(A) = \begin{bmatrix}
\tau I & (GA_n-I)Q^{-1/2} \\
(GA_n-I)Q^{-1/2} & \tau I
\end{bmatrix} + \mathcal{L}^T(G) \Delta R + \mathcal{R}^T \Delta R \mathcal{L}(G),
\]
\[
\mathcal{L}(G) = [0_{p \times n}, LG^T], \mathcal{R} = [RQ^{-1/2}, 0_{q \times n}].
\]
Invoking Theorem 3.12, the semi-infinite LMI $\mathcal{N}(A) \succeq 0 \forall A \in A$ is equivalent to
\[
\exists \lambda : \begin{bmatrix}
\lambda I_p & \rho \mathcal{L}(G) \\
\rho \mathcal{L}^T(G) & \mathcal{B}_n(G) - \lambda \mathcal{R}^T \mathcal{R}
\end{bmatrix} \succeq 0,
\]
and thus the RC is equivalent to the semidefinite program

\[
\min_{t, \tau, \lambda, G} \left\{ t : \begin{bmatrix} \lambda I_n & \tau I_n - \lambda Q^{-1/2} R^T Q^{-1/2} & \rho L G^T \\ \rho L G^T & (G_A - I_n) Q^{-1/2} & \rho L G^T \\ \rho L G^T & (G_A - I_n) Q^{-1/2} & \tau I_n \end{bmatrix} \geq 0 \right\}
\]

2): Setting \( v = U^T \hat{\nu} \), \( \hat{\gamma} = W^T y \), \( \hat{\xi} = W^T \xi \), our estimation problem reduces to the exactly the same problem, but with Diag\{a\} in the role of \( A_n \) and the diagonal matrix Diag\{q\} in the role of \( Q \); a linear estimate \( \hat{G} \hat{y} \) of \( \hat{v} \) in the new problem corresponds to the linear estimate \( U^T G W^T y \), of exactly the same quality, in the original problem. In other words, the situation reduces to the one where \( A_n \) and \( Q \) are diagonal positive semidefinite, respectively, positive definite matrices; all we need is to prove that in this special case we lose nothing when restricting \( G \) to be diagonal.

Indeed, in the case in question the RC reads

\[
\min_{t, \tau, \lambda, G} \left\{ t : \begin{bmatrix} \sqrt{\tau^2 + \delta^2} & \sqrt{\text{Tr}(G^T G)} \leq \delta \\ \lambda I_n & \tau I_n - \lambda \text{Diag}\{\mu\} \\ \rho G^T & \text{Diag}\{\nu\} - \text{Diag}\{\eta\} \end{bmatrix} \geq 0 \right\}
\]

where \( \mu_i = q_i^{-1} \), \( \nu_i = a_i/\sqrt{q_i} \) and \( \eta_i = 1/\sqrt{q_i} \). Replacing the \( G \)-component in a feasible solution with \( EGE \), where \( E \) is a diagonal matrix with diagonal entries \( \pm 1 \), we preserve feasibility (look what happens when you multiply the matrix in the LMI from the left and from the right by Diag\{1, 1, E\}). Since the problem is convex, it follows that whenever a collection \( (t, \tau, \delta, \lambda, G) \) is feasible for the RC, so is the collection obtained by replacing the original \( G \) with the average of the matrices \( E^T G E \) taken over all \( 2^n \) diagonal \( n \times n \) matrices with diagonal entries \( \pm 1 \), and this average is the diagonal matrix with the same diagonal as the one of \( G \). Thus, when \( A_n \) and \( Q \) are diagonal and \( L = R = I_n \) (or, which is the same in our situation, \( L \) and \( R \) are orthogonal), we lose nothing when restricting \( G \) to be diagonal.

Restricted to diagonal matrices \( G = \text{Diag}\{g\} \), the LMI constraint in (*) becomes a bunch of \( 3 \times 3 \) LMIs

\[
\begin{bmatrix}
\lambda & 0 & \rho g_i \\
0 & \tau - \lambda \mu_i & \nu_i g_i - \eta_i \\
\rho g_i & \nu_i g_i - \eta_i & \tau
\end{bmatrix} \geq 0, \ i = 1, ..., n,
\]

in variables \( \lambda, \tau, g_i \). Assuming w.l.o.g. that \( \lambda > 0 \) and applying the Schur Complement Lemma, these \( 3 \times 3 \) LMIs reduce to \( 2 \times 2 \) matrix inequalities

\[
\begin{bmatrix}
\tau - \lambda \mu_i & \nu_i g_i - \eta_i \\
\nu_i g_i - \eta_i & \tau - \rho^2 g_i^2/\lambda
\end{bmatrix} \geq 0, \ i = 1, ..., n.
\]

For given \( \tau, \lambda \), every one of these inequalities specifies a segment \( \Delta_i(\tau, \lambda) \) of possible value of \( g_i \), and the best choice of \( g_i \) in this segment is the point \( g_i(\tau, \lambda) \) of the segment closest to 0 (when the segment is empty, we set \( g_i(\tau, \lambda) = \infty \)). Note that \( g_i(\tau, \lambda) \geq 0 \) (why?). It follows that (*) reduces to the convex (due to its origin) problem

\[
\min_{\tau, \lambda \geq 0} \left\{ \sqrt{\tau^2 + \sigma^2 \sum_i g_i^2(\tau, \lambda)} \right\}
\]

with easily computable convex nonnegative functions \( g_i(\tau, \lambda) \).
Exercise 3.6: 1) Let $\lambda > 0$. For every $\xi \in \mathbb{R}^n$ we have $\xi^T[\rho q^T + q \rho^T]\xi = 2(\xi^T p)(\xi^T q) \leq \lambda(\xi^T p)^2 + \frac{1}{\lambda}(\xi^T q)^2 = \xi^T[\lambda pp^T + \frac{1}{\lambda}qq^T]\xi$, whence $pq^T + q \rho^T \preceq \lambda pp^T + \frac{1}{\lambda}qq^T$. By similar argument, $-pq^T \preceq \lambda pp^T + \frac{1}{\lambda}qq^T$. 1) is proved.

2) Observe, first, that if $\lambda(A)$ is the vector of eigenvalues of a symmetric matrix $A$, then $\|\lambda(pq^T + q \rho^T)\|_1 = 2\|p\|_2\|q\|_2$. Indeed, there is nothing to verify when $p = 0$ or $q = 0$; when $p, q \neq 0$, we can normalizel the situation to make $p$ a unit vector and then to choose the orthogonal coordinates in $\mathbb{R}^n$ in such a way that $p$ is the first basic orth, and $q$ is in the linear span of the first two basic orths. With this normalization, the nonzero eigenvalues of $A$ are exactly the same as the eigenvalues of the $2 \times 2$ matrix $\begin{bmatrix} 2\alpha & \beta \\ \beta & 0 \end{bmatrix}$, where $\alpha$ and $\beta$ are the first two coordinates of $q$ in our new orthonormal basis. The eigenvalues of the $2 \times 2$ matrix in question are $\alpha \pm \sqrt{\alpha^2 + \beta^2}$, and the sum of their absolute values is $2\sqrt{\alpha^2 + \beta^2} = 2\|q\|_2 = 2\|p\|_2\|q\|_2$, as claimed.

To prove 2), let us lead to a contradiction the assumption that $Y, p, q \neq 0$ are such that $Y \succeq \pm[pq^T + q \rho^T]$ and there is no $\lambda > 0$ such that $Y - \lambda pp^T - \frac{1}{\lambda}qq^T \succeq 0$, or, which is same by the Schur Complement Lemma, the LMI

$$\begin{bmatrix} Y - \lambda pp^T & q \\ q^T & \lambda \end{bmatrix} \succeq 0,$$

in variable $\lambda$ has no solution, or, equivalently, the optimal value in the (clearly strictly feasible) SDO program

$$\min_{t, \lambda} \left\{ t : \begin{bmatrix} tI + Y - \lambda pp^T & q \\ q^T & \lambda \end{bmatrix} \succeq 0 \right\}$$

is positive. By semidefinite duality, the latter is equivalent to the dual problem possessing a feasible solution with a positive value of the dual objective. Looking at the dual, this is equivalent to the existence of a matrix $Z \in \mathbb{S}^n$ and a vector $z \in \mathbb{R}^n$ such that

$$\begin{bmatrix} Z & z \\ z^T & p^T Zp \end{bmatrix} \succeq 0, \quad \text{Tr}(ZY) < 2q^T z.$$

Adding, if necessary, to $Z$ a small positive multiple of the unit matrix, we can assume w.l.o.g. that $Z \succ 0$. Setting $\bar{Y} = Z^{1/2}YZ^{1/2}$, $\bar{p} = Z^{1/2}p$, $\bar{q} = Z^{1/2}q$, $\bar{z} = Z^{-1/2}z$, the above relations become

$$\begin{bmatrix} I & \bar{z} \\ \bar{z}^T & \bar{p}^T \bar{p} \end{bmatrix} \succeq 0, \quad \text{Tr}(\bar{Y}) < 2\bar{q}^T \bar{z}. \quad (*)$$

Observe that from $Y \succeq \pm[pq^T + q \rho^T]$ it follows that $\bar{Y} \succeq \pm[\bar{p}\bar{q}^T + \bar{q}\bar{p}^T]$. Looking at what happens in the eigenbasis of the matrix $[\bar{p}\bar{q}^T + \bar{q}\bar{p}^T]$, we conclude from this relation that $\text{Tr}(\bar{Y}) \geq \|\lambda(pq^T + q \rho^T)\|_1 = 2\|\bar{p}\|_2\|\bar{q}\|_2$. On the other hand, the matrix inequality in $(*)$ implies that $\|\bar{z}\|_2 \leq \|\bar{p}\|_2$, and thus $\text{Tr}(\bar{Y}) < 2\|\bar{p}\|_2\|\bar{q}\|_2$ by the second inequality in $(*)$. We have arrived at a desired contradiction.

3) Assume that $x$ is such that all $L_\ell(x)$ are nonzero. Assume that $x$ can be extended to a feasible solution $Y_1, \ldots, Y_L, x$ of (3.7.2). Invoking 2), we can find $\lambda_\ell > 0$ such that $Y_\ell \succeq \lambda_\ell R_\ell^T R_\ell + \frac{1}{\lambda_\ell} L_\ell^T (x) L_\ell(x)$. Since $A_\ell(x) - \rho \sum_\ell Y_\ell \succeq 0$, we have $|A_\ell(x) - \rho \sum_\ell \lambda_\ell R_\ell^T R_\ell - \sum_\ell \frac{1}{\lambda_\ell} L_\ell^T (x) L_\ell(x) \succeq 0$, whence, by the Schur Complement Lemma, $\lambda_1, \ldots, \lambda_L, x$ are feasible for (3.7.3). Vice versa, if $\lambda_1, \ldots, \lambda_L, x$ are feasible for (3.7.3), then $\lambda_\ell > 0$ for all $\ell$ due to $L_\ell(x) \neq 0$, and, by the same Schur Complement Lemma, setting $Y_\ell = \lambda_\ell R_\ell^T R_\ell + \frac{1}{\lambda_\ell} L_\ell^T (x) L_\ell(x)$, we have

$$A_\ell(x) - \rho \sum_\ell Y_\ell \succeq 0,$$
while \( Y_\ell \succeq \pm [L_\ell^T(x)R_\ell + R_\ell^T L_\ell(x)] \), that is, \( Y_1, \ldots, Y_L, x \) are feasible for (3.7.2).

We have proved the equivalence of (3.7.2) and (3.7.3) in the case when \( L_\ell(x) \neq 0 \) for all \( \ell \). The case when some of \( L_\ell(x) \) vanish is left to the reader.

**Exercise 3.7:** A solution might be as follows. The problem of interest is
\[
\min_{G,t} \{ t : t \geq \| (GA - I)v + G\xi \|_2 \forall (v, \xi \in \Xi, A \in \mathcal{A}) \}
\]

\[
\min_{G,t} \left\{ t : u^T(GA - I)v + u^T G\xi \leq t \forall \left( \begin{array}{c}
u \leq 1 \\
v^T P v \leq 1,
\end{array} \right) \right\}, \quad (*)
\]

Observing that
\[
u^T [GA - I]v + u^T G\xi = [u; v; \xi^T]^T \begin{bmatrix}
\frac{1}{2}[GA - I] & \frac{1}{2} G \\
\frac{1}{2}[GA - I]^T & \frac{1}{2} G^T
\end{bmatrix} [u; v; \xi],
\]

for \( A \) fixed, a sufficient condition for the validity of the semi-infinite constraint in (*) is the existence of nonnegative \( \mu, \nu_i, \omega_j \) such that
\[
\begin{bmatrix}
\mu I \\
\sum_i \nu_i P_i \\
\sum_j \omega_j Q_j
\end{bmatrix} \succeq \begin{bmatrix}
\frac{1}{2}[GA - I] & \frac{1}{2} G \\
\frac{1}{2}[GA - I]^T & \frac{1}{2} G^T
\end{bmatrix}
\]

and \( \mu + \sum_i \nu_i + \rho \sum_j \omega_j \leq t \). It follows that the validity of the semi-infinite system of constraints
\[
\mu + \sum_i \nu_i + \rho \sum_j \omega_j \leq t, \quad \mu \geq 0, \nu_i \geq 0, \omega_j \geq 0
\]

\[
\begin{bmatrix}
\mu I \\
\sum_i \nu_i P_i \\
\sum_j \omega_j Q_j
\end{bmatrix} \succeq \begin{bmatrix}
\frac{1}{2}[GA - I] & \frac{1}{2} G \\
\frac{1}{2}[GA - I]^T & \frac{1}{2} G^T
\end{bmatrix}
\]

(!!)

in variables \( t, G, \mu, \nu_i, \omega_j \) is a sufficient condition for \((G,t)\) to be feasible for (*). The only semi-infinite constraint in (!!) is in fact an LMI with structured norm-bounded uncertainty:

\[
\begin{bmatrix}
\mu I \\
\sum_i \nu_i P_i \\
\sum_j \omega_j Q_j
\end{bmatrix} \succeq \begin{bmatrix}
\frac{1}{2}[GA - I] & \frac{1}{2} G \\
\frac{1}{2}[GA - I]^T & \frac{1}{2} G^T
\end{bmatrix}
\]

\[
+ \sum_{\ell=1}^L B_{\ell(\mu,\nu,\omega, G)} [L_\ell(G) \Delta_\ell R_\ell + R_\ell^T \Delta_\ell^T L_\ell(G)] \succeq 0 \quad \forall (\| \Delta_\ell \|_{2,2} \leq \rho, 1 \leq \ell \leq L),
\]

\[
L_\ell(G) = \frac{1}{2} [L_\ell G^T, 0_{p_L \times n}, 0_{p_L \times m}], \quad R_\ell = [0_{q_L \times n}, R_\ell, 0_{q_L \times m}].
\]
Invoking Theorem 3.13, we end up with the following safe tractable approximation of $(*)$:

$$\min_{t,G,\mu,\nu,\omega,\lambda, Y} \ t$$

s.t.

$$\mu + \sum_{i} \nu_i + \rho^2 \sum_{j} \omega_j \leq t, \quad \mu \geq 0, \nu_i \geq 0, \omega_j \geq 0$$

$$\left[ \begin{array}{c} \lambda I - \sum_{\ell=1}^{L} Y_{\ell} - \lambda_{\ell} R_{\ell}^{T} R_{\ell} \\ -B(\mu, \nu, \omega, G) - \rho A \sum_{\ell=1}^{L} Y_{\ell} \end{array} \right] \geq 0, \quad 1 \leq \ell \leq L$$

$$B(\mu, \nu, \omega, G) - \rho A \sum_{\ell=1}^{L} Y_{\ell} \geq 0.$$
Exercise 4.2: 1) With $\phi(\rho) = \tau u + \alpha \rho$ problem (!) does not make sense, meaning that it is always infeasible, unless $E = \{0\}$. Indeed, otherwise $g$ contains a nonzero vector $g$, and assuming (!) feasible, we should have for certain $\tau$ and $\alpha$

$$\begin{bmatrix} 2(\tau + \alpha \rho) \\ f + \rho g \end{bmatrix} \begin{bmatrix} f^T + \rho g^T \\ A(t) \end{bmatrix} \succeq 0 \forall \rho > 0$$

or, which is the same,

$$\begin{bmatrix} 2\rho^{-1} \tau + 2\rho^{-1} \alpha \\ \rho^{-1} f + g \end{bmatrix} \begin{bmatrix} \rho^{-1} f^T + g^T \\ A(t) \end{bmatrix} \succeq 0 \forall \rho > 0.$$

passing to limit as $\rho \to +\infty$, the matrix $\begin{bmatrix} 0 & g^T \\ g & A(t) \end{bmatrix}$ should be $\succeq 0$, which is not the case when $g \neq 0$.

The reason why the GRC methodology does not work in our case is pretty simple: we are not applying this methodology, we are doing something else. Indeed, with the GRC approach, we would require the validity of the semidefinite constraints

$$\begin{bmatrix} \tau \\ f + \rho g \end{bmatrix} \begin{bmatrix} f^T + \rho g^T \\ A(t) \end{bmatrix} \succeq 0, \quad f \in \mathcal{F}, g \in E$$

for all $f \in \mathcal{F}$ in the case of $\rho = 0$ and were allowing “controlled deterioration” of these constraints when $\rho > 0$:

$$\text{dist} \left( \begin{bmatrix} \tau \\ f + \rho g \end{bmatrix} \begin{bmatrix} f^T + \rho g^T \\ A(t) \end{bmatrix}, S_{m+1} \right) \leq \alpha \rho \forall (f \in \mathcal{F}, g \in E).$$

When $\tau$ and $\alpha$ are large enough, this goal clearly is feasible. In the situation described in item 1) of Exercise, our desire is completely different: we want to keep the semidefinite constraints feasible, compensating for perturbations $\rho g$ by replacing the compliance $\tau$ with $\tau + \alpha \rho$. As it is shown by our analysis, this goal is infeasible – the “compensation in the value of compliance” should be at least quadratic in $\rho$.

2) With $\phi(\rho) = (\sqrt{\tau} + \sqrt{\alpha \rho})^2$, problem (!) makes perfect sense; moreover, given $\tau \geq 0$, $\alpha \geq 0$, $t \in \mathcal{T}$ is feasible for (!) if and only if the system of relations

\[ (a) \quad \begin{bmatrix} 2\tau \\ \rho \end{bmatrix} \begin{bmatrix} f^T \\ A(t) \end{bmatrix} \succeq 0 \forall f \in \mathcal{F} \]

\[ (b) \quad \begin{bmatrix} 2\alpha \\ g \end{bmatrix} \begin{bmatrix} g^T \\ A(t) \end{bmatrix} \succeq 0 \forall g \in E \]

Since $\mathcal{F}$ is finite, (a) is just a finite collection of LMIs in $t, \tau$; and since $E$ is a centered at the origin ellipsoid, the results of section 3.4.2 allow to convert the semi-infinite LMI (b) into an equivalent tractable system of LMIs, so that (a), (b) is computationally tractable.

The claim that $t$ is feasibly for the semi-infinite constraint

$$\begin{bmatrix} 2(\sqrt{\tau} + \sqrt{\alpha \rho})^2 \\ f + \rho g \end{bmatrix} \begin{bmatrix} f^T + \rho g^T \\ A(t) \end{bmatrix} \succeq 0 \forall (f \in \mathcal{F}, g \in E, \rho \geq 0)$$

if and only if $t$ satisfies (a) and (b) is evident. Indeed, if $t$ is feasible for the latter semi-infinite LMI, $t$ indeed satisfies (a) and (b) – look what happens when $\rho = 0$ and when $\rho \to \infty$. Vice versa, assume that $t$ satisfies (a) and (b), and let us prove that $t$ satisfies (*) as well. Indeed,
given $\rho > 0$, let us set $\mu = \frac{\sqrt{r}}{\sqrt{r} + \rho \nu}$, $\nu = 1 - \mu = \frac{\rho \nu}{\sqrt{r} + \rho \nu}$ and $s = \frac{\nu}{\mu}$. For $f \in F$ and $g \in E$ from (a), (b) it follows that

$$\begin{bmatrix} 2\tau f^T \\ f \end{bmatrix} A(t) \succeq 0, \begin{bmatrix} 2s^2 \alpha \\ sg \end{bmatrix} A(t) \succeq 0;$$

or, which is the same by the Schur Complement Lemma, for every $\epsilon > 0$ one has

$$\|[A(t) + \epsilon I]^{-1/2} f\|_2 \leq \sqrt{2\tau}, \|[A(t) + \epsilon I]^{-1/2} g\|_2 \leq \sqrt{2\alpha},$$

whence, by the triangle inequality,

$$\|[A(t) + \epsilon I]^{-1/2}[f + \rho g]\|_2 \leq \sqrt{2\tau} + \sqrt{2\alpha}\rho,$$

meaning that

$$\begin{bmatrix} 2s^2 \alpha \\ sg \end{bmatrix} A(t) \succeq 0.$$

The latter relation holds true for all $(\epsilon > 0, f \in F, g \in E)$, and thus $t$ is feasible for $(*)$.

**Exercise 4.3:** 1) The worst-case error of a candidate linear estimate $g^T y$ is

$$\max_{z, \xi : \|z\|_2 \leq 1, \|\xi\|_2 \leq 1} \|(Az + \xi)^T g - f^T z\|_2,$$

so that the problem of building the best, in the minimax sense, estimate reads

$$\min_{\tau, G} \{ \tau : |(Az + \xi)^T g - f^T z| \leq \tau \forall [z; \xi] : \|z\|_2 \leq 1, \|\xi\|_2 \leq 1 \},$$

which is nothing but the RC of the uncertain Least Squares problem

$$\begin{cases} \min_{\tau, G} \{ \tau : (Az + \xi)^T g - f^T z \leq \tau, f^T z - (Az + \xi)^T g \leq \tau \} : \zeta := [z; \xi] \in \mathcal{Z} = B \times \Xi \end{cases}$$

in variables $g, \tau$ with certain objective and two constraints affinely perturbed by $\zeta = [z; \xi] \in B \times \Xi$. The equivalent tractable reformulation of this RC clearly is

$$\min_{\tau, g} \{ \tau : \|At^T g - f\|_2 + \|g\|_2 \leq \tau \}.$$
by $\mathcal{Z}_\xi = \Xi$, $\mathcal{L}_\xi = \mathbb{R}^m$ and the norm on $\mathbb{R}^m$ is $\|\cdot\|_2$. Invoking Proposition 4.2, $g$ is feasible for our GRC if and only if

$$(a) \quad (Az + \xi)^T g - f^T z \in Q \quad \forall (z \in B, \xi \in \Xi)$$

$$(b.1) \quad |(A^T g - f)^T z| \leq \alpha_z \quad \forall (z : \|z\|_2 \leq 1)$$

$$(b.2) \quad |\xi^T g| \leq \alpha_\xi \quad \forall (\xi : \|\xi\|_2 \leq 1)$$

or, which is the same, $g$ meets the requirements if and only if

$$\|A^T g - f\|_2 + \|g\|_2 \leq \tau, \quad \|A^T g - f\|_2 \leq \alpha_z, \quad \|g\|_2 \leq \alpha_\xi.$$  

**Exercise 4.4:** 1) The worst-case error of a candidate linear estimate $Gy$ is

$$\max_{z, \xi : \|z\|_2 \leq 1, \|\xi\|_2 \leq 1} \|G(Az + \xi) - Cz\|_2,$$

so that the problem of building the best, in the minimax sense, estimate reads

$$\min_{\tau, G} \left\{ \tau : \|G(Az + \xi) - Cz\|_2 \leq \tau \quad \forall ([z; \xi] : \|z\|_2 \leq 1, \|\xi\|_2 \leq 1) \right\},$$

which is nothing but the RC of the uncertain Least Squares problem

$$\left\{ \min_{\tau, G} \left\{ \tau : \|G(Az + \xi) - Cz\|_2 \leq \tau \right\} : \xi := [z; \xi] \in \mathcal{Z} = B \times \Xi \right\}$$

in variables $G, \tau$. The body of the left hand side of the uncertain constraint is

$$G(Az + \xi) - Cz = L_1^T(G)zR_1 + L_2^T(G)\xi R_2,$$

that is, we deal with structured norm-bounded uncertainty with two full uncertain blocks: $n \times 1$ block $z$ and $m \times 1$ block $\xi$, the uncertainty level $\rho$ being 1 (see section 3.3.1). Invoking Theorem 3.4, the system of LMIs

$$\begin{bmatrix}
  u_0 - \lambda & u^T \\
  u & U & GA - C^T \\
  v_0 - \mu & v^T \\
  v & V & G^T \\
  \tau - u_0 - v_0 & -u^T - v^T \\
  -u - v & \tau I - U - V
\end{bmatrix} \succeq 0,$$  

in variables $G, \tau, \lambda, \mu, u_0, u, U, v_0, v, V$ is a tight within the factor $\pi/2$ safe tractable approximation of the RC.

2) Now we want of our estimate to satisfy the relations

$$\forall (\rho_z \geq 0, \rho_\xi \geq 0) : \|G(Az + \xi) - Cz\|_2 \leq \tau + \alpha_z \rho_z + \alpha_\xi \rho_\xi, \quad \forall (z : \|z\|_2 \leq 1 + \rho_z, \xi : \|\xi\|_2 \leq 1 + \rho_\xi),$$

or, which is the same,

$$\forall [z; \xi] : \|G(Az + \xi) - Cz\|_2 \leq \tau + \alpha_z \text{dist}_{\|\cdot\|_2}(z, B) + \alpha_\xi \text{dist}_{\|\cdot\|_2}(\xi, \Xi).$$
This is exactly the same as to say that $G$ should be feasible for the GRC of the uncertainty-affected inclusion

$$G(Az + \xi) - Cz \in Q = \{ w : \|w\|_2 \leq \tau \}$$

in the case where the uncertain perturbations are $[z; \xi]$, the perturbation structure for $z$ is given by $Z_z = B, L_z = \mathbb{R}^n$, the perturbation structure for $\xi$ is given by $Z_\xi = \Xi, L_\xi = \mathbb{R}^m$, the global sensitivities w.r.t. $z, \xi$ are, respectively, $\alpha_z, \alpha_\xi$, and all norms in the GRC setup are the standard Euclidean norms on the corresponding spaces. Invoking Proposition 4.2, $G$ is feasible for our GRC if and only if

(a) $\|G(Az + \xi) - Cz\|_2 \in Q \ orall (z \in B, \xi \in \Xi)$

(b) $\|GA - C\|_2 \leq \alpha_z \ \forall (z : \|z\|_2 \leq 1)$

(c) $\|G\xi\|_2 \leq \alpha_\xi \ \forall (\xi : \|\xi\|_2 \leq 1)$.

(b), (c) merely say that $\|GA - I\|_2, \|G\|_2 \leq \alpha_z, \alpha_\xi$,

while (a) admits the safe tractable approximation $(S)$.

### B.5 Exercises from Lecture 5

**Exercise 5.1:** From state equations (5.5.1) coupled with control law (5.5.3) it follows that

$$w^N = W_N[\Xi]\zeta + w_N[\Xi],$$

where $\Xi = \{U_i^z, U_i^d, u_0^I\}_{t=0}^N$ is the “parameter” of the control law (5.5.3), and $W_N[\Xi], w_N[\Xi]$ are matrix and vector affinely depending on $\Xi$. Rewriting (5.5.2) as the system of linear constraints

$$e_j^T w^N - f_j \leq 0, \ j = 1, ..., J,$$

and invoking Proposition 4.1, the GRC in question is the semi-infinite optimization problem

$$\min_{\Xi, \alpha} \alpha$$

subject to

$$e_j^T [W_N[\Xi]\zeta + w_N[\Xi]] - f_j \leq 0 \ \forall (\zeta : \|\zeta - \bar{\zeta}\|_s \leq R) \ \ (a_j)$$

$$e_j^T W_N[\Xi]\zeta \leq \alpha \ \forall (\zeta : \|\zeta\|_r \leq 1) \ \ (b_j)$$

$$1 \leq j \leq J.$$

This problem clearly can be rewritten as

$$\min_{\Xi, \alpha} \alpha$$

subject to

$$R \|W_N^T[\Xi]e_j\|_{s*} + e_j^T [W_N[\Xi]\zeta + w_N[\Xi]] - f_j \leq 0, \ 1 \leq j \leq J \ \ \|W_N^T[\Xi]e_j\|_{r*} \leq \alpha, \ 1 \leq j \leq J$$

where

$$s* = \frac{s}{s - 1}, \ r* = \frac{r}{r - 1}.$$
Exercise 5.2: The AAGRC is equivalent to the convex program

\[
\begin{align*}
\min_{\Xi, \alpha} \quad & \alpha \\
\text{subject to} \quad & R \| W^T N \Xi e_j \|_{s_*} + e_j^T \left( W N [\Xi] \xi + w N [\Xi] - f_j \right) \leq 0, 1 \leq j \leq J \\
& \| \left( W N [\Xi] e_j \right)_{d,+} \|_{r_*} \leq \alpha, 1 \leq j \leq J
\end{align*}
\]

where

\[
s_*= \frac{s}{s-1}, \quad r_* = \frac{r}{r-1}
\]

and for a vector \( \zeta = [z; d_0; \ldots; d_N] \in \mathbb{R}^K \), \( [\zeta]_{d,+} \) is the vector obtained from \( \zeta \) by replacing the \( z \)-component with 0, and replacing every one of the \( d \)-components with the vector of positive parts of its coordinates, the positive part of a real \( a \) being defined as \( \max[a, 0] \).

Exercise 5.3: 1) For \( \zeta = [z; d_0; \ldots; d_{15}] \in \mathbb{Z} + \mathcal{L} \), a control law of the form (5.5.3) can be written down as

\[
u_t = \nu^0_t + \sum_{\tau=0}^t u_{\tau} d_{\tau},
\]

and we have

\[
x_{t+1} = \sum_{\tau=0}^t \left[ u^0_{\tau} - d_{\tau} + \sum_{s=0}^\tau u_{\tau s} d_s \right] = \sum_{\tau=0}^t u^0_{\tau} + \sum_{s=0}^t \left[ \sum_{\tau=s}^t u_{\tau s} - 1 \right] d_s.
\]

Invoking Proposition 4.1, the AAGRC in question is the semi-infinite problem

\[
\begin{align*}
\min_{\{u^0_t, u_{\tau}\}, \alpha} \quad & \alpha \\
\text{subject to} \quad & (a_x) \quad |\theta \left[ \sum_{\tau=0}^t u^0_{\tau} \right] | \leq 0, 0 \leq t \leq 15 \\
& (a_u) \quad |u^0_t| \leq 0, 0 \leq t \leq 15 \\
& (b_x) \quad |\theta \left[ \sum_{s=0}^t \nu_{\tau s} - 1 \right] d_s | \leq \alpha \\
& \quad \forall (0 \leq t \leq 15, [d_0; \ldots; d_{15}] : \| [d_0; \ldots; d_{15}] \|_2 \leq 1) \\
& (b_u) \quad |\sum_{\tau=0}^t u_{\tau} d_{\tau}| \leq \alpha \\
& \quad \forall (0 \leq t \leq 15, [d_0; \ldots; d_{15}] : \| [d_0; \ldots; d_{15}] \|_2 \leq 1)
\end{align*}
\]

We see that the desired control law is linear (\( u^0_t = 0 \) for all \( t \)), and the AAGRC is equivalent to the conic quadratic problem

\[
\min_{\{u_{\tau}\}, \alpha} \left\{ \alpha : \sqrt{\sum_{s=0}^t \sum_{\tau=s}^t u_{\tau s} - 1}^2 \leq -1 \alpha, 0 \leq t \leq 15 \right\}.
\]

2) In control terms, we want to “close” our toy linear dynamical system, where the initial state is once and for ever set to 0, by a linear state-based non-anticipative control law in such a way that the states \( x_1, \ldots, x_{16} \) and the controls \( u_1, \ldots, u_{15} \) in the closed loop system are “as insensitive to the perturbations \( d_0, \ldots, d_{15} \) as possible,” while measuring the changes in the state-control trajectory

\[
u_{15} = [0; x_1; \ldots; x_{16}; u_1, \ldots, u_{15}]
\]

in the weighted uniform norm \( \| \nu_{15} \|_{\infty, \theta} = \max[\theta, \| x \|_{\infty}, \| u \|_{\infty}] \), and measuring the changes in the sequence of disturbances \( [d_0; \ldots; d_{15}] \) in the “energy” norm \( \|[d_0; \ldots; d_{15}]\|_2 \). Specifically, we are
interested to find a linear non-anticipating state-based control law that results in the smallest possible constant \( \alpha \) satisfying the relation

\[
\forall \Delta d^{15} : \| \Delta w^{15} \|_{\infty, \theta} \leq \alpha \| \Delta d^{15} \|_2,
\]

where \( \Delta d^{15} \) is a shift of the sequence of disturbances, and \( \Delta w^{15} \) is the induced shift in the state-control trajectory.

3) The numerical results are as follows:

<table>
<thead>
<tr>
<th>( \theta )</th>
<th>( \alpha )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.6</td>
<td>4.0000</td>
</tr>
<tr>
<td>10</td>
<td>3.6515</td>
</tr>
<tr>
<td>2</td>
<td>2.8284</td>
</tr>
<tr>
<td>1</td>
<td>2.3094</td>
</tr>
</tbody>
</table>

**Exercise 5.4:** 1) Denoting by \( x_{ij}^\gamma \) the amount of information in the traffic from \( i \) to \( j \) travelling through \( \gamma \), by \( q_\gamma \) the increase in the capacity of arc \( \gamma \), and by \( O(k), I(k) \) — the sets of outgoing, resp., incoming, arcs for node \( k \), the problem in question becomes

\[
\min_{\{x_{ij}^\gamma\}_{(i,j)}} \left\{ \sum_{(i,j) \in J} x_{ij}^\gamma \leq p_\gamma + q_\gamma \forall \gamma \right\} 
\]

\[
\sum_{\gamma \in O(k)} x_{ij}^\gamma - \sum_{\gamma \in I(k)} x_{ij}^\gamma = \left\{ \begin{array}{ll}
d_{ij}, & k = i \\
-d_{ij}, & k = j \\
0, & k \notin \{i,j\}
\end{array} \right\} ; \\
q_\gamma \geq 0, x_{ij}^\gamma \geq 0 \forall ((i,j) \in J, k \in V)
\]

2) To build the AARC of (*) in the case of uncertain traffics \( d_{ij} \), it suffices to plug into (*) instead of decision variables \( x_{ij}^\gamma \), affine functions \( X_{ij}^\gamma(d) = \xi_{ij}^{\gamma,0} + \sum_{(\mu,\nu) \in J} \xi_{ij}^{\gamma,\mu\nu} d_{\mu\nu} \) of \( d = \{d_{ij} : (i,j) \in J\} \) (in the case of (a), the functions should be restricted to be of the form \( X_{ij}^\gamma(d) = \xi_{ij}^{\gamma,0} + \xi_{ij}^{\gamma} d_{ij} \)) and to require the resulting constraints in variables \( q_\gamma, \xi_{ij}^{\gamma} \) to be valid for all realizations of \( d \in Z \). The resulting semi-infinite LO problem is computationally tractable (as the AARC of an uncertain LO problem with fixed recourse, see section 5.3.1).

3) Plugging into (*), instead of variables \( x_{ij}^\gamma \), affine decision rules \( X_{ij}^\gamma(d) \) of the just indicated type, the constraints of the resulting problem can be split into 3 groups:

\[
\begin{align*}
(a) \quad & \sum_{(i,j) \in J} X_{ij}^\gamma(d) \leq p_\gamma + q_\gamma \forall \gamma \in \Gamma \\
(b) \quad & \sum_{(i,j) \in \Gamma} R_{ij}^\gamma X_{ij}^\gamma(d) = r(d) \\
(c) \quad & q_\gamma \geq 0, X_{ij}^\gamma(d) \geq 0 \forall ((i,j) \in J, \gamma \in \Gamma).
\end{align*}
\]

In order to ensure the feasibility of a given candidate solution for this system with probability at least \( 1 - \epsilon, \epsilon < 1 \), when \( d \) is uniformly distributed in a box, the linear equalities (b) must be satisfied for all \( d \)'s, that is, (b) induces a system \( A_\xi = b \) of linear equality constraints on the vector \( \xi \) of coefficients of the affine decision rules \( X_{ij}^\gamma(\cdot) \). We can use this system of linear equations, if it is feasible, in order to express \( \xi \) as an affine function of a shorter vector \( \eta \) of “free” decision variables, that is, we can easily find \( H \) and \( h \) in such a way that \( A_\xi = b \) is equivalent to the existence of \( \eta \) such that \( \xi = H \eta + h \). We can now plug \( \xi = H \eta + h \) into (a), (c) and forget about (b), thus ending up with a system of constraints of the form

\[
\begin{align*}
(a') \quad & a_\ell(q, \eta) + a_\ell^T(q, \eta)d \leq 0, \ 1 \leq \ell \leq L = \text{Card}(\Gamma)(\text{Card}(J) + 1), \\
(b') \quad & q \geq 0
\end{align*}
\]
with $a_\ell, \alpha_\ell$ affine in $[\eta; q]$ (the constraints in $(a')$ come from the Card($\Gamma$) constraints in $(a)$ and the Card($\Gamma$)Card($\mathcal{J}$) constraints $X_{ij}^d(d) \geq 0$ in $(c)$).

In order to ensure the validity of the uncertainty-affected constraints $(a')$, as evaluated at a candidate solution $[\eta; q]$, with probability at least $1 - \epsilon$, we can use either the techniques from Lecture 2, or the techniques from section 3.6.4.
