HW 1 Solution

1. (20 pts)
\( D = 5000/\text{yr}, \ C = 600/\text{unit}, \ 1\ \text{year} = 300\ \text{days}, \ i = 0.06, \ A = 300 \)
Current ordering amount \( Q = 200 \)

(a) \( T^* = \frac{Q}{D} \times 300\text{days} = \frac{200}{5000} \times 300 = 12 \text{ days} \)

(b) Total(Holding + Setup) cost would be
\[
TC = \frac{iC}{2} Q + \frac{D}{Q} A = \frac{0.06 \times 600}{2} \times 200 + \frac{5000}{200} \times 300 = 11,100/\text{yr}
\]

(c) The optimum cost would be
\[
\sqrt{2ADh} = \sqrt{2 \times 300 \times 5000 \times 0.06 \times 600} = 10392.30/\text{yr}
\]

(d) \( T^* \) is 12 days. The closest power of two is 16 days(16/300 yr).
\[
\text{TC(16 days)} = \frac{TDh}{2} + \frac{A}{T} = \frac{16}{200} \times 5000 \times 0.06 \times 600 + \frac{300}{16} \times 300 = 10425/\text{yr}
\]
The power of two on the other side of 12 days is 8 days(8/300 yr).
\[
\text{TC(8 days)} = \frac{TDh}{2} + \frac{A}{T} = \frac{8}{200} \times 5000 \times 0.06 \times 600 + \frac{300}{8} \times 300 = 13650/\text{yr}
\]

2. (20 pts)
\( D = 200/\text{month} = 2400/\text{yr}, \ A = (100+55)\times 1.5 = 232.5 \)
\( P = 50/\text{hr} = 50 \times 6 \times 20 \times 12/\text{yr} = 72000/\text{yr}, \ i = 0.22, \ C = 2.50 \)

(a) \( Q^* = \frac{2AD}{\sqrt{h(1-D/P)}} = \frac{2 \times 232.5 \times 2400}{\sqrt{0.22 \times 2.50 \times (1-\frac{2400}{72000})}} = 1448.8 \approx 1449 \)

(b) \( H = Q^* \left(1 - \frac{D}{P}\right) = 1449 \times \left(1 - \frac{2400}{72000}\right) = 1400.7 \approx 1401 \)

(c) \( \frac{D}{P} = \frac{2400}{72000} = 0.0333 = 3.33\% \)
3. (20 pts)

(a)
EOQ of A : \[
\sqrt{\frac{2 \times 100 \times 200}{0.2 \times 2.5}} = 2828.42 \approx 2828 \rightarrow Q_A = 2828
\]
EOQ of B : \[
\sqrt{\frac{2 \times 100 \times 200}{0.2 \times 2.4}} = 2886.75 \approx 2887 \rightarrow Q_B = 3000
\]
EOQ of C : \[
\sqrt{\frac{2 \times 100 \times 200}{0.2 \times 2.3}} = 2948.84 \approx 2948 \rightarrow Q_C = 4000
\]
Therefore, optimal order quantity is 4000 with source C.

(b) 
Holding + Setup cost = \(100 \times \frac{20000}{4000} + 0.2 \times 2.3 \times \frac{4000}{2} = 1420\)

(c) 
Cycle Time = \(\frac{4000}{20000} = 0.2\) year = 2.4 months.
Replenishment lead time = 3 months.
Reorder point = \(3/2.4 \times 4000 = 5000 \rightarrow 1000\) units is reorder point

It is interesting to interpret the above result for part (c) in terms of the definition of the Inventory Position \(IP(t)\) introduced in class during the discussion of the Stochastic Inventory Control theory. So, remember that
\[
IP(t) = OHI(t) + O(t) - BO(t)
\]
where
- \(OHI(t)\) denotes the on-hand-inventory at time \(t\);
- \(O(t)\) denotes the “pipeline” inventory at time \(t\) (i.e., material ordered but not received yet);
- \(BO(t)\) denotes the backorders at time \(t\).

Also, let \(Q_l = lD\) denote the demand experienced over a replenishment lead time interval \(l\). In our case, this quantity is \(Q_l = (3/12) \times 20000 = 5000\).

Since we want to have no shortages,
\[BO(t) = 0 \text{ for all } t\] (2)

Consider also the \(OHI(t)\) at any time \(t\), and notice that at time \(t+l\),
OHI(t+1) – BO(t+1) = OHI(t) + O(t) – Q_i \quad (3)

Furthermore, in the light of (1), Equation (3) becomes

OHI(t+1) – BO(t+1) = IP(t) – Q_i \quad (4)

Since t was chosen arbitrarily, Equation (4) implies that we shall have BO(t) = 0 for all t, as long as

IP(t) \geq Q_i \text{ at all } t \quad (5)

The condition of Equation (5) can be satisfied in a way that minimizes the incurred holding cost, by setting the reorder point with respect to the IP(t) signal equal to Q_i (since, in this case, every time that IP(t) gets to the Q_i level, we place a replenishment order and we increase IP(t) by Q_i).

Finally, the reorder point with respect to OHI(t) is provided from the reorder point with respect to IP(t) through (1), when noticing that BO(t) = 0.

The main lesson of the above discussion is that in the EOQ context, reorder points should be specified according to the formula

\text{ROP} = \frac{1}{2} D

but with respect to the inventory position, and not the on-hand-inventory.

4. (20 pts)
Order quantity given data

<table>
<thead>
<tr>
<th>Item</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>12,500</td>
<td>15,000</td>
<td>15,000</td>
</tr>
<tr>
<td>A</td>
<td>150</td>
<td>80</td>
<td>80</td>
</tr>
<tr>
<td>h</td>
<td>2.4</td>
<td>3.5</td>
<td>3</td>
</tr>
<tr>
<td>Unit. Stor(f_i)</td>
<td>5</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>EOQ</td>
<td>1250</td>
<td>828.0786712</td>
<td>894.427191</td>
</tr>
<tr>
<td>Stor. Need</td>
<td>6250</td>
<td>3312.314685</td>
<td>3577.708764</td>
</tr>
<tr>
<td>Total Storage</td>
<td>13140.02345</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Since total required storage area is over 6000 sq. ft., we need to adjust order quantities. We can find the optimal order quantities through the search process over the Lagrange multiplier \( \lambda \), discussed in class, that computes the values

\[ Q_i = \sqrt{\frac{2A_iD_i}{h_i + 2\lambda f_i}} \]

and checks whether they satisfy the resource constraint as equality.
After some search on the values of $\lambda$, we get: $\lambda^* = 1.204799$

<table>
<thead>
<tr>
<th>Item</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>12,500</td>
<td>15,000</td>
<td>15,000</td>
</tr>
<tr>
<td>A</td>
<td>150</td>
<td>80</td>
<td>80</td>
</tr>
<tr>
<td>h</td>
<td>2.4</td>
<td>3.5</td>
<td>3</td>
</tr>
<tr>
<td>Unit. Stor\text{f}_j</td>
<td>5</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>NEW Q</td>
<td>509.4621425</td>
<td>427.3999954</td>
<td>435.7723896</td>
</tr>
<tr>
<td>Stor. Need 2</td>
<td>2547.310713</td>
<td>1709.599982</td>
<td>1743.089559</td>
</tr>
<tr>
<td>Total Storage</td>
<td>6000.000253</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Thus, the optimized order quantities for item 1, 2, and 3 should be 509, 427, and 436, respectively. As discussed in class, $-\lambda^*$ denotes the derivative of the optimal cost with respect to the size of the storage area $F$, and therefore, we should not be willing to pay more than 1.2 dollars per extra sq. ft.

5. (20 pts)

<table>
<thead>
<tr>
<th>Time</th>
<th>1</th>

<tr>
<td>Order Quantity</td>
<td>40</td>
<td>225</td>
<td>125</td>
<td>60</td>
<td>413.75</td>
<td></td>
</tr>
</tbody>
</table>

Also, notice that according to the “Planning Horizon” theorem of the Wagner-Whitin algorithm, we could have skipped the calculation of all the cells in each column \( j \in \{1, \ldots, 6\} \), that lies above the highlighted cell in column \( j-1 \), without compromising the identification of the optimal plan (i.e., in columns 3 and 4, we could have skipped the evaluation of their first cells, and in columns 5 and 6 we could have skipped the evaluation of the first three cells).

Finally, in the considered application context, we could have used the Planning Horizon theorem to incur even larger economies in the involved computations. The point is that, under the applied “rolling-horizon” scheme, all we really want to know is the size of the order that should be placed in the first period. Now, according to the Planning Horizon theorem, if the demand \( d_i \) at some period \( j>1 \) is ordered at period \( i>1 \), then the demand \( d_k \) for any other period \( k>j \) will also be ordered at a period \( i'>1 \). Hence, we can stop the entire computation as long as we find such a period \( j \) (in the considered example, we could have stopped at the second period – in practice, typically we want to complete the calculation since having the entire ordering plan gives us some visibility on how our future needs are going to shape up).

**Extra Credit (25 pts)**

We are given the following information, annual demand = 140 units, ordering cost = 30 per order, holding cost = 18%, and cost function

\[
C(Q) = \begin{cases} 
350Q & : 1 \leq Q \leq 25, \\
8750 + 315(Q - 25) & : 26 \leq Q \leq 50, \\
16625 + 285(Q - 50) & : 51 \leq Q.
\end{cases}
\]

Then we have,

\[
\frac{C(Q)}{Q} = \begin{cases} 
350 & : 1 \leq Q \leq 25, \\
315 + \frac{875}{Q} & : 26 \leq Q \leq 50, \\
285 + \frac{2375}{Q} & : 51 \leq Q.
\end{cases}
\]

The total annual cost function, \( G(Q) \), that is implied by the above average unit costs, is given by:

\[
G(Q) = \frac{DC(Q)}{Q} + AD + \frac{h}{2} \left( \frac{C(Q)}{Q} \right) Q.
\]

The \( Q \)'s that minimize this last function for each of the three expressions of \( C(Q)/Q \)
can be obtained by substituting each of these three expressions in $G(Q)$ and computing the minimum of the resulting function. This procedure gives us:

$$
Q(1) = 12 \\
Q(2) = 67 \\
Q(3) = 115
$$

Observing that $Q(2)$ does not fall into the correct interval, we focus only on the total annual costs that are provided by $Q(1)$ and $Q(2)$:

$$
G(Q(1)) = (350)(140) + \frac{(30)(140)}{12} + \frac{(0.18)(350)(12)}{2} = 49728
$$

$$
G(Q(3)) = \left(285 + \frac{2375}{115}\right)(140) + \frac{(30)(140)}{115} + \frac{(0.18)\left(285 + \frac{2375}{115}\right)(115)}{2} = 45991
$$

Since $Q = 115$ results in a lower cost, company Y should use an order size of 115 units.
